LIHOVÁ, J. & MARHOLD, K., Chromosome numbers and distribution of *Cardamine amara* (Brassicaceae) in Slovenia. Biologia, Bratislava, 58: 37—43, 2003; ISSN 0006-3088.

Chromosome numbers and distribution of two subspecies of *Cardamine amara* in Slovenia are presented. Major part of Slovenia is occupied by tetraploid *C. amara* subsp. *austriaca*, the taxon with the distribution centered in the Eastern Alps. In Slovenia it prevails in the (Pre)alpine and (Pre)dinaric regions and approaches the southern limit of its known distribution area. Diploid *C. amara* subsp. *amara* is in Slovenia less frequent, it is concentrated in the northeastern Subpannonian region. Morphological differences between these two subspecies, especially those in the pollen grain size are mentioned. Distribution pattern found in Slovenia and the assumed evolutionary history of the tetraploid subspecies are discussed.

Key words: Alps, autoploidy, *Cardamine amara* subsp. *amara*, *Cardamine amara* subsp. *austriaca*, Dinaric region, distribution map, Subpannonian region.

Introduction

Cardamine amara L. is a morphologically highly variable species widespread in Europe and extending to Asia. It occupies moist to wet sites mainly on stream banks and springs from lowlands up to the alpine belt. Based on previous taxonomic studies, several diploid and two tetraploid subspecies are currently recognized within this species in Europe. The subspecies are morphologically and geographically well characterized (MARHOLD, 1992, 1998, 1999a; MARHOLD et al., 1996; LIHOVÁ et al., 2000).

The typical subspecies, diploid *C. amara* subsp. *amara*, is the most common and widespread subspecies, it is distributed in a major part of the species distribution area (JALAS & SUOMI-

NEN, 1994). Recently, the tetraploid subspecies *C. amara* subsp. *austriaca* MARHOLD was described, occurring in the Eastern Alps and neighbouring areas (MARHOLD, 1999a). Morphometric and molecular (isozymes, RAPDs, AFLPs) investigation showed that this represents most probably young autotetraploid derivative of *C. amara* subsp. *amara* (MARHOLD, 1999a, LIHOVÁ et al., 2000, MARHOLD et al., 2002). The tetraploid occupies a rather compact distribution area, where *C. amara* subsp. *amara* is generally lacking; these two subspecies only marginally overlap in the western (eastern Switzerland) and northern parts (southern Bohemia) of the area of subsp. Morphologically it is very close to *C. amara* subsp. *amara*, and only a combination of several morphological characters (number of leaves, length of sepals and

Alpsko območje, Maribor, Brestrnica, at the Bresterški potok brook, 350 m alt., MTB 9459/1, 21 April 2001, coll. J. LIHOVÁ & B. FRAJMAN. – 2n = 32

filaments, branching of stem and especially diameter of pollen grains) separates it from this taxon (MARHOLD, 1999a).

Another tetraploid taxon from Catalonia, NE Spain traditionally treated as *C. amara* subsp. *olotensis* O. BOLÒS (BOLÒS, 1952; BOLÒS et al., 1993; RICO, 1993) has been recently shown to be distant from the core *C. amara*, and should be classified as a separate species – *Cardamine amporitana* SENNEN & PAU (LIHOVÁ et al., 2000; MARHOLD et al., 2002; LIHOVÁ et al., submitted). Other diploid subspecies are confined to certain European mountain ranges, namely *C. amara* subsp. *opiciei* (J. PRESL & C. PRESL) ČELAK. to the Sudety Mts. and the Carpathians, *C. amara* subsp. *balcanica* MARHOLD, ANČEV & KIT TAN to the mountains of SW Bulgaria and NE Greece, and *C. amara* subsp. *pyrenaica* SENNEN to the Eastern Pyrenees (MARHOLD, 1992, 1998; MARHOLD et al., 1996; LIHOVÁ et al., 2000).

In Slovenia, occurrence of both *C. amara* subsp. *amara* and *C. amara* subsp. *austriaca* has been reported (MARHOLD, 1999a,b), but no detailed karyological or chorological investigation has been done here as yet. In the distribution atlas of Slovenia (JOGAN, 2001) only general distribution of *C. amara* was given, without subspecific separation. According to this, *C. amara* occurs throughout the whole area of Slovenia, but it is more concentrated in northern and northeastern parts of the country. The area of Slovenia seems to represent the southern limit of distribution of *C. amara* subsp. *austriaca*, thus its exploration was expected to bring more precise delimitation of the area occupied by this tetraploid. In this paper we deal with the detailed distribution pattern of *C. amara* subsp. *amara* and *C. amara* subsp. *austri-*

aca in the area studied.

Material and methods

For chromosome number determination, six samples of *Cardamine amara* originating from several phytogeographical regions in Slovenia were collected (Tab. 1). The plants collected in the field were cultivated at the Institute of Botany, Slovak Academy of Sciences, and their root tips were treated using the squash method (modified after MÁRTONFI et al., 1999). The root tips were pretreated in 0.002 mol/L aqueous solution of 8-hydroxyquinoline for 3 hrs at 4°C, fixed for 1 hr in a mixture of 96% ethanol and concentrated acetic acid (3:1), hydrolyzed in a mixture of concentrated hydrochloric acid and 96% ethanol (1:1) for 3 min, and finally squashed using a celophane piece instead of the cover glass. The squashes were stained in 10% Giemsa stock solution in Sörensen phosphate buffer for 1 hr, and rinsed with distilled water. The voucher specimens of the karyologically examined populations are deposited at SAV (herbarium abbreviations follow HOLMGREN et al., 1990).

Chorological study was based on our own samples (Tab. 1), on the previously published data (MARHOLD, 1999a), and on herbarium specimens deposited at LJU and SAV (Appendix). The specimens from LJU were determined at the subspecific level by measuring pollen grain diameter. From each specimen, one flower bud was removed and pollen grains were stained using acetocarmine-jelly (KEARNS & INOUYE, 1993). Thirty pollen grains were measured from one flower and average values of pollen grain diameter were calculated. These were compared with the values of karyologically investigated plants both from Slovenia (Tab. 1) and other regions (voucher specimens from the paper by MARHOLD, 1999a). For diploid *C. amara* subsp. *amara* we recorded pollen grains of 18.0–20.4 µm, whereas those of *C. amara* subsp. *austriaca* were 20.6–24.7 µm large (average values of 30 pollen grains per one plant). A slight shift of both these ranges compared

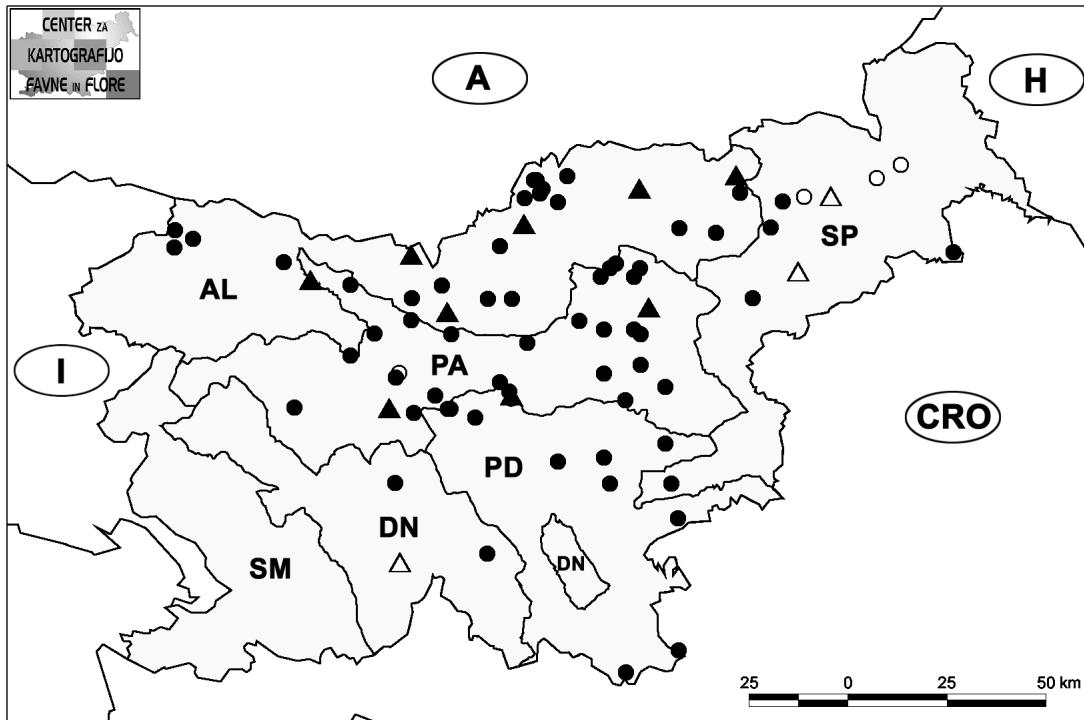

Fig. 1. Distribution of diploid *Cardamine amara* subsp. *amara* (empty symbols) and tetraploid *C. amara* subsp. *austriaca* (solid symbols) in Slovenia. Circles represent records based on investigation of herbarium specimens (see Appendix), triangles depict populations karyologically investigated in this study and that of MARHOLD (1999a). Phytogeographical regions: AL – Alpine, PA – Prealpine, SP – Subpannonian, PD – Predinaric, DN – Dinaric, SM – Submediterranean. A – Austria, H – Hungary, CRO – Croatia, I – Italy. The map was produced in the Center za kartografijo favne in flore, Ljubljana, Slovenia.

with the previously published data for these two subspecies (MARHOLD, 1999a,b) was caused most probably by the use of another measuring equipment.

Results and discussion

Out of six karyologically investigated populations from Slovenia, five were tetraploid ($2n = 32$) and a single one was diploid ($2n = 16$), corresponding to *Cardamine amara* subsp. *austriaca* and *C. amara* subsp. *amara*, respectively (Tab. 1). The diploid population of *C. amara* subsp. *amara* was found in the eastern Subpannonian part of the country (Subpanonsko območje: Trnovska vas), whereas the tetraploid populations of *C. amara* subsp. *austriaca* originated from Alpine and Prealpine regions (Alpsko območje, Predalpsko območje). MARHOLD (1999a) reported previously two localities of *C. amara* subsp. *amara* from eastern (Subpanonsko območje: Ptujska gora) and southern Slovenia (Dinarsko območje: Pudob),

and tetraploid *C. amara* subsp. *austriaca* from the northern Alpine region. Evaluation of herbarium specimens deposited at LJU and SAV (Appendix) revealed more detailed distribution pattern of the studied taxa. As can be seen from the map (Fig. 1), the area of Slovenia is mostly inhabited by tetraploid *C. amara* subsp. *austriaca*, which in few cases extends also to the most southern (Bela Krajina) and eastern regions (Ptujsko polje). Diploid *C. amara* subsp. *amara* is concentrated in the northeastern Subpannonian area, except for two sites found in the Ljubljanska kotlina basin, and one, already mentioned site in the south. Similar distribution pattern was found for diploid *C. matthioli* MORETTI of the *C. pratensis* group, which in Slovenia occurs mainly in the Subpannonian region, partly extending to the most eastern parts of the Alpine, Prealpine and Predinaric regions, with a few localities in the Ljubljanska kotlina basin (LIHOVÁ & MARHOLD, submitted). Whereas diploid *C. amara* subsp. *amara* rep-

resents in Slovenia mainly Subpannonian floristic element, tetraploid subsp. *austriaca* overwhelmingly prevails in the regions of (Pre)alpine and (Pre)dinaric flora. When comparing our results with the general distribution of *C. amara* in Slovenia (JOGAN, 2001), there are few scattered records also in the Submediterranean region in the southwestern part of the country, which, however, lack in the map presented here (Fig. 1). We have not seen any herbarium specimen from that region, and search in several quadrants in 1994 was unsuccessful. More detailed exploration on the occurrence of *C. amara* in that area and its subspecific affiliation would be desirable.

Cardamine amara subsp. *austriaca* has its distribution centre in the Eastern Alps in Austria, however it extends also to neighbouring regions. The eastern boundary of the distribution area was found in eastern Austria, where the area of this taxon only slightly overlaps with that of diploid *C. amara* subsp. *amara*. A somewhat larger overlap was observed in the west in eastern Switzerland (MARHOLD 1999a) and in the north (S Bohemia), where tetraploids reach as far as to the phytogeographical district Bréznické Podbrdsko, to the south of the town of Příbram (MARHOLD, unpubl.). Nevertheless, in both regions of overlap *C. amara* subsp. *austriaca* tends to occupy higher altitudes than *C. amara* subsp. *amara* (MARHOLD, 1999a). This seems to be to certain extent also the case of Slovenian populations – diploid *C. amara* subsp. *amara* occurs mainly in the region of lower altitudes, seldom up to 570 m a.s.l., although the populations of *C. amara* subsp. *austriaca* in the most southern and eastern parts of the country grow also at rather low altitudes of ca. 180–200 m a.s.l. (see Appendix). The localities of *C. amara* subsp. *amara* in Slovenia continuously append to those in southeastern Austria (Burgenland and Styria) (MARHOLD, 1999a). There are no chromosome records for *C. amara* from the countries more to the south (Croatia, Bosnia and Herzegovina) so far, where both *C. amara* subsp. *amara* and *C. amara* subsp. *austriaca* could occur, as we assume from the distribution pattern in Slovenia. It is worth to mention that in the neighbouring regions of Upper Styria (Austria) and northern Italy populations currently classified as *C. amara* subsp. *austriaca* were previously misidentified as *C. amara* subsp. *opizii* (PIGNATTI, 1982; MAURER, 1996) and from Slovenia itself subsp. *opizii* was wrongly reported by LÖVE & LÖVE (1974) (as *C. opizii*).

Cardamine amara subsp. *amara* and subsp. *austriaca* are morphologically very close to each

other. Previous morphometric analyses revealed only minor morphological differences between them. Tetraploid *C. amara* subsp. *austriaca* tends to have more leaves, less branched stem, larger flowers (longer petals, sepals and filaments of stamens), and especially, larger pollen grains. The last mentioned character is the only one which reliably differentiates individual plants of subsp. *amara* and subsp. *austriaca* (MARHOLD, 1999a). When ploidy level is not known, measurement of pollen grain is often inevitable for proper determination of single plants, but prior this, calibration based on measurements of plants with known ploidy level is recommended (see Material and Methods).

In agreement with morphology, also molecular data (RAPDs, AFLPs, isozymes) have shown very close position of both subspecies, as even such sensitive markers as AFLPs and RAPDs have not provided sufficient differentiation between them, and samples of both subspecies appeared in an unresolved polytomy (LIHOVÁ et al., 2000; MARHOLD et al., 2002).

In recent years, arctic and alpine plants have been intensively studied in respect of their interglacial migrations and postglacial recolonization during the Quaternary (COMES & KADEREIT, 1998). The Alps represent a region covered to a large extent by ice sheets during the glacial periods, and plants occurring here, their distribution and genetic diversity, were strongly affected by these climatic changes (STEHLÍK, 2000). Phylogeographic studies, based on exploration of geographic distribution of genetic diversity, aim to trace evolutionary history and diversification of various taxa, discussing *in situ* persistence on ice-free nunataks (e.g. STEHLÍK et al., 2001) versus survival in peripheral refugial regions with subsequent recolonization (e.g. GUGERLI et al., 2001). *Cardamine amara* subsp. *austriaca* is one of the taxa confined to the Eastern Alps and adjacent regions, and its origin is believed to be strongly associated with Pleistocene glaciation of the Alps (MARHOLD, 1999a). Low genetic and morphological divergence from the typical subspecies suggests a recent autopolyploid origin of this taxon, originated from *C. amara* subsp. *amara* (MARHOLD, 1999a; LIHOVÁ et al., 2000; MARHOLD et al., 2002). Retreat of ice sheet after the last glaciation period offered uncovered areas with various unsettled habitats. This might have supported spread and establishment of tetraploid populations of *C. amara* subsp. *austriaca* in the Eastern Alps. However, as yet there is no information on possible colonization routes,

nor whether monotypic or polytopic origin of this subspecies should be considered. A more detailed phylogeographic study could elucidate these questions.

Acknowledgements

We are grateful to our colleagues from Ljubljana for their help and accompanying during the fieldwork in Slovenia: Nejc JOGAN, Branka TRČAK, Tinka BAČIČ and Božo FRAJMAN. The Center za kartografsko favne in flore, Ljubljana, Slovenia (Branka TRČAK) is acknowledged for generating the distribution map. This study was financially supported by project no. 7080 from the Grant Agency VEGA, Bratislava, Slovak Republic, and project no. 1131-4 from the Ministry of Education, Youth and Sports of the Czech Republic.
